Abstract
Tetralogy of Fallot is the most common cyanotic congenital heart disease. The first complete repair of tetralogy of Fallot was successfully performed by C. Walton Lillehi and his team in 1954, but first total correction performed at department of cardiothoracic and vascular surgery Amiri Medical Complex Kabul Afghanistan in 2015, despite some advocates of routine two-stage repair in infancy, during the early 1990s reports documented improve early results with primary repair was associated with improved outcome compared to a two-stage approach. The purpose of this study was to analyze the early postoperative result in total correction for the first time in Afghanistan.

Method: The purpose of this study was to evaluate the early outcome after total correction in 180 consecutive patients with a mean age of 5-30 years who underwent total correction surgery in a single center Amiri Medical Complex, Kabul, Afghanistan between August 2015 and October 2018. 8 patients had initial palliative operations (modified BT shunt) in outside centers and referred to us for total correction. The trans annular pericardial patch was inserted in 133(73.8%) patients. 32(17.7%) patients repaired by trans atrial total correction (ventricular septal defect, right ventricular outflow tract muscle band resection and pulmonary valvotomy done through the right atrium ) for 5(2.7%) patients with absent pulmonary valve, monocuspid and bicuspid pulmonary valve reconstructed with a pericardial patch.

Result: Mean follow up was (1-3) months postoperatively, the mortality rate was (8.8%). Most of the patients who repaired with trans annular patch had free pulmonary valve regurgitation post-operative period by transthoracic echocardiography 26 patients had the excellent function of their native repaired pulmonary valve and monocusp, bicuspid reconstructed pulmonary valve. The peak gradient of right ventricular outflow tract was between 10 to 35 mmHg postoperatively. 22 patients had small (tiny) residual ventricular septal defect and none of the patients had complete heart block (0%).

Conclusion: Total correction for tetralogy of Fallot patients may have low operative mortality and provide excellent short and long term survival in modern centers; this experience suggests that total correction for tetralogy of Fallot patients would have good short term outcomes in developed countries.

Introduction
The first complete repair of tetralogy of Fallot was successfully performed by C. Walton Lillehi and his team in 1954 [1-5]. The purpose of this study was to analyze early postoperative and early result in total correction of tetralogy of fallot at the department of cardiothoracic surgery Amiri medical complex for the first time in Afghanistan.

Patients and Methods

Patients
Between August 2015 to September 2018, 180 consecutive patients with Tetralogy of Fallot (TOF) (pink TOF Spo2>80% in room air and blue TOF Spo2<80% in room air) underwent total correction for Tetralogy of Fallot at department of cardiothoracic and vascular
surgery Amiri medical complex Kabul Afghanistan for the first time, there were 101(56.1%) male patient and 79(43.8%) were female patients with age of 5 to 30 years and weight was (9-55 kg).

This includes a patient with classic tetralogy of Fallot and associated pathologic processes such as atrial septal defect, patent ductus arteriosus and absent pulmonary valve, etc. (Table 1). There were just 8(4.4%) patients with primary palliative procedures (modified BT shunt) were referred to us for total correction from outside centers. The diagnosis of tetralogy of Fallot for all patients was made by transthoracic echocardiography, CT angiography and cardiac catheterization (Table 2) [6].

Data collection

From a review of the medical record, the follow up was achieved in 156(86.6%) patients in the cardiology clinic, mean follow up was 30-90 days post-operative.

Operative procedure

The heart exposed through a median sternotomy a patch of the pericardium was removed for ventricular septal defect repair and right ventricular outflow tract reconstruction, pulmonary artery trunk with branches dissected.

The operation was performed under cardiopulmonary bypass with mild hypothermia (nasopharyngeal temperature of 30-32°C), intermittent doses of cold cardioplegia (del Nido cardioplegia) were used for myocardial protection, right atriotomy was used to expose the ventricular septal defect and right ventricular outflow tract muscle band resection.

In trans right atrium total correction, ventricular septal defect, right ventricular outflow tract muscle band resection and pulmonary valve commissurotomy were done through the right atrium [7]. Ventricular septal defect patch was sewn by continuous suture [8], the right ventricular outflow tract and pulmonary artery were enlarged with autologous pericardium in [9] 133(73.8%) patients, monocuspid and bicuspid pulmonary valve reconstructed with autologous pericardium in 15(8.3%) patients. In case of right or left pulmonary artery stenosis bicuspid pulmonary valve reconstructed with autologous pericardium in [9] 133(73.8%) patients, monocuspid and bicuspid pulmonary valve) with pericardial patch had good function of reconstructed valve pulmonary valve reconstruction (bicusp and monocusp pulmonary valve) with pericardial patch had good function of reconstructed valve with mild pulmonary valve regurgitation, 32(17.7%) patients who required permanent pacemaker implantation in the perioperative period, postoperative complication shown in (Table 3).

Results

Early result

Overall mortality rate was (8.8%) 16 patients, 4 patients died due to severe bleeding (pulmonary hemorrhage, 2 patients because of right ventricular failure, 3 patients died due to multi-organ failure, 4 patients because of sepsis, in 3 patients ventricular septal defect patch dehiscence occurred and they died because of heart failure (patients attendant were not agreed with reoperation) there was not on table death.

Aortic cross-clamp time was (30-45min) and cardiopulmonary bypass time was (55-75min), factors affecting operative survival were analyzed, aortic cross-clamp time and cardiopulmonary bypass time not affected operative survival.

The previous palliative procedure did not adversely affect operative mortality.

Among operative measurement construction of the right ventricular outflow tract with a patch was not related to early mortality [10], perioperative measurement of hematocrits level was significantly related to early mortality and perioperative thrombocytopenia was the great risk factor for postoperative mortality [11,12].

Postoperative ventilation more than 48 hours than tracheostomy was necessary for 3(1.6%) patients, transient right heart failure required inotropic support for 72 hours occurred in 18(10%) patients, use of temporary pacemaker was required in 13(7.2%) patients, no patient required permanent pacemaker implantation in the perioperative period, postoperative complication shown in (Table 3).

The median length of stay in the intensive care unit was 2-8 days, the median hospital stay was 4-16 days.

Residual anatomical defect was first diagnosed by clinical and echocardiographic or both, 22 patients had a tiny residual Venticular Septal Defect (VSD) and most of the patients with trans annular patch had free pulmonary valve regurgitation, 5(2.7%) patients with pulmonary valve reconstruction (bicusp and monocusp pulmonary valve) with pericardial patch had good function of reconstructed valve with mild pulmonary valve regurgitation, 32(17.7%) patients who repaired trans right atrium total correction had excellent function of pulmonary valve and right ventricle function.

Discussion

Despite total correction of tetralogy of Fallot being a common cardiac surgical procedure for more than 50 years, [13] some controversy still exists regarding the optimal treatment method [14]. Some groups advocated routine two staged procedure for tetralogy

</table>
of Fallot with a shunt for symptomatic patients during infancy and total correction within 1.5 years of palliation [7]. Other investigators propose selective staged management with initial shunting particularly in patients with less than ideal anatomy [15]. However patients with undergoing staged treatment of tetralogy of Fallot using a palliative shunt and subsequent total correction accrue the risk of two operative procedure and the potential complications of right to left intracardiac shunting, compromised ventricular function and fibrosis with ongoing hypoxemia and myocardial ischemia [16]. The selective operative treatment of tetralogy of Fallot has developed from previous surgical failure and surgical successes with the operative management of various subsets of patients with the tetralogy Fallot [17].

We originally thought that significantly higher operative mortality might be found in those patients with the most severe intracardiac malformation and high hematocrit [18] especially in our center because of lack of experience and poor facilities, despite all problems for the first time we would be able to publish our data and our early postoperative mortality is quite acceptable regarding most experienced centers.

Conclusion

There is general agreement that the best treatment of patients with tetralogy of Fallot is complete repair in infancy which may reduce the incidence of late electrophysiological and hemodynamic problem and improve survival [19]. The trans atrial approach is a feasible technique for total correction of tetralogy of Fallot patients inadequate pulmonary annulus size according to Z score with satisfactory echocardiography performance of late postoperative right ventricle and pulmonary valve functions [20]. We evaluated hemodynamics of 26 patients who repaired trans atrial total correction or pulmonary valve reconstructed by pericardial patch they had an excellent function of their reconstructed pulmonary valve with no or mild regurgitation and very good right ventricle function.
